

MUSEUM COLLECTIONS

Scientific collections held in the world's museums are vital repositories of the world's biodiversity. Scrutiny of museum specimens helps scientists document nature's diversity—and can even uncover species that were previously unknown. The olinguito was described as new on the basis of skins and skulls in the American Museum of Natural History. These specimens had previously been identified as olingos of the genus *Bassaricyon*, but careful comparison of their features and dimensions revealed them to be a new species of this genus, subsequently named the olinguito.
