

ends of the firetubes. Ash drawn through the firetubes collects here.

STEAM LOCOMOTION

Steam locomotion is founded on the principle that when water is heated above its boiling point, it turns to steam and its volume becomes 1,700 times greater. When this expansion takes place within a sealed vessel such as a boiler, the pressure of the steam becomes a source of energy.

SWITCH

Trackwork mechanism at the point where two tracks diverge, allowing a train to move from one track to another.

TANK LOCOMOTIVE

A steam engine that carries its fuel and water on its own chassis rather than on a separate tender. Water is held in side tanks or in saddle tanks that carry the boiler. *See also* Tender.

TENDER

A vehicle attached to a steam engine that carries fuel and water.

TRACK

Rails, ballast, and fastenings that supply a runway for the wheels of a train.

TRACTION

A force that relies on friction between a wheel and a rail to generate motion.

TRAIN

A form of transport that either has passenger, freight, or both vehicles put together, travelling as one unit along a rail line. Trains are either self-propelled or hauled by a locomotive.

VACUUM BRAKE
