

Polaroid camera

Three-year-old Jennifer Land asked her father why a photo couldn't be seen right after it was taken. The question led **EDWIN LAND** to invent the Polaroid camera in 1947, which worked by using chemicals inside the camera to **develop** and print the image. For the first time, people could see their photos without having to send the film away to be developed.

The photograph comes out of the front of the camera, as the image is developing.

Celluloid camera film is used by film cameras to record the picture. The film must then be developed to see the picture.

Introduced in 1909, 35mm camera film is still used today.

The screen allows you to see the image before you capture it. It also shows stored pictures.

Digital camera

Digital photography is **absolutely instant** and doesn't require film or processing. The Japanese company Sony sold the first commercial filmless camera in 1981. It used a **DISK DRIVE** to store video-camera images, but was otherwise like a normal camera. As technology got better and the cost of the components went down, the first digital cameras began to be sold. It wasn't long before almost everyone was snap-happy: Digital cameras allow you to take and save as many pictures as you want, printing out only your favorites.
