

How it works

The program rearranges the order of letters in the message so that it can't be understood. It does this by working out which letters are in even or odd positions. Then it swaps the position of each pair of letters in the message, starting with the first two, then the next two, and so on. The program also makes encrypted messages readable again by switching the letters back to where they started.

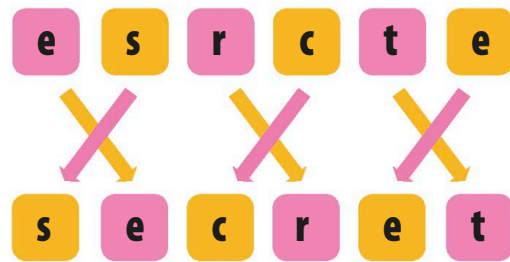

In Python (which counts in a weird way, starting from 0), the first letter in the word is in an even position.

△ Encryption

When you run the code on your message, the program swaps each pair of letters, scrambling the meaning.

△ Decryption

When you or a friend decrypt the message, the program swaps the letters back to their original positions.
