

Circuits of power

An electric circuit is a loop that electricity can travel around. An electric current moves through the wires in this circuit and lights up the bulb.

hands on

Rub a party balloon up and down on your clothes. The balloon will now stick to the wall. This is because rubbing it gives the balloon an electric charge.

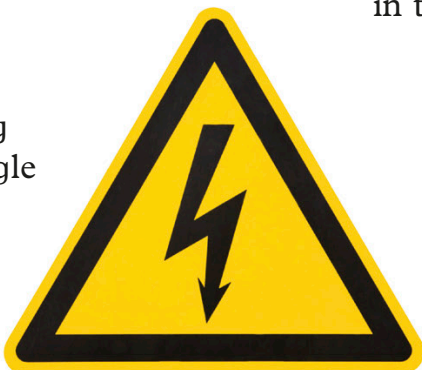

Lightning strikes

Electric charge building up in one place is called “static electricity.” Lightning is an electric current caused by static electricity building up in thunderclouds.

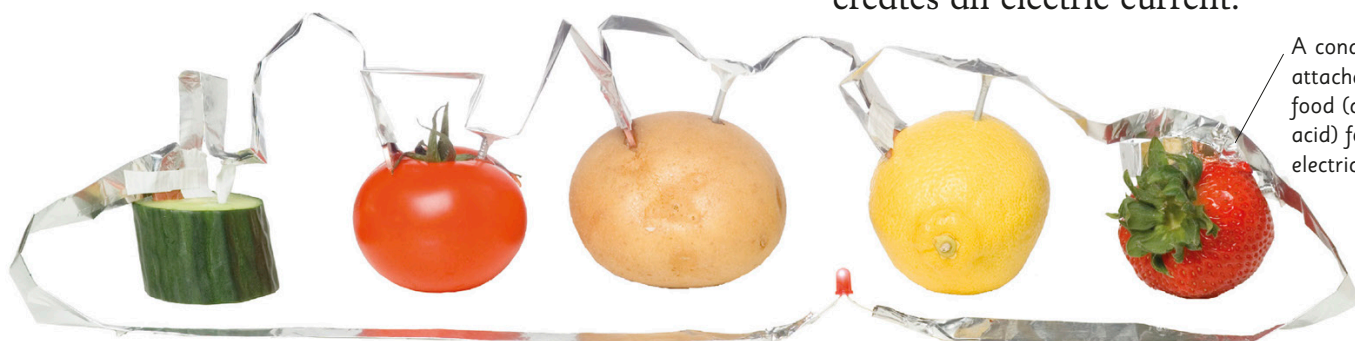

High voltage

Electricity can be very dangerous. This triangle is an international warning symbol. It means “Caution: risk of electric shock.”

Food battery

Food that contains water and weak acid will conduct electricity. In a food battery, a chemical reaction between the metal and the acid in the food creates an electric current.

A conductor attached to food (containing acid) forms an electric circuit.
