

Bees and wasps

You may think bees and wasps simply buzz a lot and sting, but they are actually some of the most intelligent insects around.

Bees

Bumblebees and honeybees live in large colonies, working together as a group. Worker bees spend much of their lives gathering nectar from plants, which they turn into honey.

Bumblebees do not produce large amounts of honey.

weird or what?

When a honeybee knows that a flower is full of nectar, it does a special wagging dance to show other worker bees where to go to collect it.

The bee has special baskets on its legs to collect pollen in.

Worker bees cannot lay eggs. Only the queen provides new babies.

Honey is their food.

Class system

Bee societies have three classes within their colony.

Queen: each bee colony has a queen who lays up to 100 eggs a day.

Drone: there are only ever a few drones – males – with the queen.

Worker: all of the workers are female. They collect the nectar.

Comb

A honeybee's home is a miniature city made of wax, produced by the bees, in cell shapes. This is called a honeycomb. Some cells hold a baby larva and some hold honey.
