

Webs

All spiders produce silk from inside their abdomen. Most weave nests or webs with it, while jumping spiders use it to anchor themselves to one object while they leap to another.

Spiders build their webs and wait patiently for insects to fly into them. They then wrap the insects in jackets of silk, and eat them.

Water spiders even make underwater webs that keep an air bubble in place.

Water spiders

Most spiders live on land but a few, such as the water spider, live underwater. To breathe, it traps air inside a bubble, which it anchors to plants.

Most spiders remain with their eggs, looking after them until they have hatched.

Egg sac

Eggs and babies

Spider's silk is also used to build nests or to attach eggs to the spider to carry around. This spider, however, holds the eggs in her jaws until they hatch.

Most spiders have eight eyes!
