

Songbirds

Most of the world's birds are part of a huge family known as the songbirds. They spend a lot of their time in flight.

Foot perch

Songbirds, or perchers, all have a unique type of foot, which helps them to grip onto even the thinnest branches. Three of their toes point forwards and one points backwards.

The short beak is used to crack hard foods, such as nutshells.

Songbirds can sleep on twigs and branches without falling off.

Blue tit

A variety of birds

Members of the songbird family vary in looks, habits, and songs.

Robin: European robins are easy to spot because of their red tummies.

Blackbird: the blackbird often sings in the evenings from a high perch.

Warbler: these birds are known for their different songs, including a scolding song.

Finding food

Like this song thrush, most songbirds are small, but because they use up a lot of energy flying, they need a lot of food. They feed on small insects, worms, and snails.
